

Description

[METHOD OF ASSESSING POTENTIAL FOR CHARGING DAMAGE IN SOI DESIGNS AND STRUCTURES FOR ELIMINATING POTENTIAL FOR DAMAGE]

BACKGROUND OF INVENTION

[0001] Field of the Invention.

[0002] The present invention generally relates to protection circuitry and more particularly to a method and structure that includes a shunt device between the source/drain and gate of SOI transistors which may develop a voltage differential between the source/drain and gate during wafer fabrication. The shunt device eliminates the potential for charging damage from processing.

[0003] Description of Related Art.

[0004] One problem that exists when designing integrated circuits with silicon-over-insulator (SOI) transistors relates to the detection of which SOI transistors may be suscepti-

ble to charging damage, and to providing protection once such a susceptible device is identified. In SOI it is not possible to "tie down" a floating gate in the traditional sense, such as by adding a diode connection to the substrate or nwell. SOI technologies are inherently less susceptible to charging damage because both the source/drain and the gate tend to have similar antennae, so the potential of both nodes varies together. This is not, however, certain in all cases. The invention described below is designed to detect and modify the integrated circuit design to eliminate the possibility of charging damage.

SUMMARY OF INVENTION

- [0005] The invention provides a method of altering an integrated circuit design having silicon over insulator (SOI) transistors. The invention prevents damage from a potential difference between the source/drain and gate of SOI transistors by tracing electrical nets in the integrated circuit design, identifying SOI transistors that may have a voltage differential between the source/drain and gate as potentially damaged SOI transistors (based on the tracing of the electrical nets), and connecting a shunt device across the source/drain and the gate of each of the potentially damaged SOI transistors. In addition, the invention can also

connect compensating antennae to each of the nodes to balance the charging and eliminate the potential for damage.

- [0006] The shunt device and the compensating conductor eliminate the potential for charging damage to the gate of each of the potentially damaged SOI transistors. The tracing process is performed assuming all metals and diffusions are conductive. The tracing, the identifying, and the connecting processes are repeated at each level of wiring within the integrated circuit design.
- [0007] The invention compares aspect ratios of vias connected to the source/drain and the gate of each of the SOI transistors to determine whether a voltage differential might exist between the source/drain and the gate. Alternatively, the invention can compare chip locations of conductors connected to the source/drain and the gate of each of the SOI transistors to determine whether a voltage differential might exist between the source/drain and the gate. Also, the invention can compare parasitic capacitances of conductors connected to the source/drain and the gate of each of the SOI transistors to determine whether a voltage differential might exist between the source/drain and the gate.

- [0008] The foregoing process produces a protection circuit for an integrated circuit device that includes silicon over insulator (SOI) transistors and has a shunt device connected from the source/drain to the gate of at least one of the SOI transistors. The structure can also include a compensating conductor connected to one or the other or both of the source/drain or gate of the susceptible device through a series device. The series device and the compensating conductor eliminate the potential for charging damage between the source/drain and the gate of the SOI transistor. Further, the shunt and the series devices perform no function other than eliminating the potential for charging damage. The shunt and series device could be, for example, an FET connected as a diode.
- [0009] The shunt device should be positioned in parallel with the SOI transistor. Thus, the shunt device can be positioned between a first conductor connected to the source/drain of the SOI transistor and a second conductor connected to the gate of the SOI transistor. Alternatively, the series device can be positioned between a first conductor connected to the SOI transistor and a second conductor that is not connected to the SOI transistor. Also, the invention can further include a second shunt device, wherein the

shunt device is connected to a first conductor and the second shunt device is connected to a second conductor, where the first conductor is connected to the source/drain of the SOI transistor and the second conductor is connected to the gate of the SOI transistor.

- [0010] These, and other, aspects and objects of the present invention will be better appreciated and understood when considered in conjunction with the following description and the accompanying drawings. It should be understood, however, that the following description, while indicating preferred embodiments of the present invention and numerous specific details thereof, is given by way of illustration and not of limitation. Many changes and modifications may be made within the scope of the present invention without departing from the spirit thereof, and the invention includes all such modifications.

BRIEF DESCRIPTION OF DRAWINGS

- [0011] The invention will be better understood from the following detailed description with reference to the drawings, in which:
- [0012] Figure 1 is a schematic diagram of a SOI circuit;
- [0013] Figure 2 is a schematic diagram of a SOI circuit with a

shunt;

- [0014] Figure 3 is a schematic diagram of a SOI circuit with series devices; and
- [0015] Figure 4 is a flow diagram illustrating a method of the invention.

DETAILED DESCRIPTION

- [0016] The present invention and the various features and advantageous details thereof are explained more fully with reference to the nonlimiting embodiments that are illustrated in the accompanying drawings and detailed in the following description. It should be noted that the features illustrated in the drawings are not necessarily drawn to scale. Descriptions of well-known components and processing techniques are omitted so as to not unnecessarily obscure the present invention in detail. The examples used herein are intended merely to facilitate an understanding of ways in which the invention may be practiced and to further enable those of skill in the art to practice the invention. Accordingly, the examples should not be construed as limiting the scope of the invention.
- [0017] As mentioned above, even SOI design structures produce the possibility of charging damage. For example, it is possible to create a differential antenna by the arrange-

ment of vias within the metal line. Vias placed in narrow metal lines have a larger aspect ratio than vias placed well within large metal plates, and may therefore charge to a different potential when exposed to a plasma. This occurs in either via-first or trough-first processes, although the specific sensitive process then varies. If the gate and source/drain have different via/metal configurations, then charging damage can occur.

- [0018] To address this problem, the invention traces electrical nets assuming that metals and diffusions (even when they are cut by an FET gate) are conductive, determines the characteristics of the charge-collecting antennas on each node of each FET, assesses the potential for charging damage on each device. Where appropriate, a shunt device and/or a compensating antenna, perhaps connected through a series device, is placed to eliminate the potential for charging damage.
- [0019] More specifically, the vias on each node (gate and source/drain) of each FET are categorized and counted. The source and drain of each transistor have the same potential during the processing. Therefore, the source and drain are considered synonymous in this application and are sometimes referred to herein as a single unit using the

terminology "source/drain." The conductive connections to the gate and source/drain are identified as either a high-aspect ratio or low-aspect ratio via examining their shapes and locations with respect to the edge of the metal wire. The effective net on each node is determined by considering all FETs to be conductive (this is a realistic assumption as there is large leakage from each source/drain to the floating well, particularly under the typical processing conditions of elevated temperature and in the presence of photons). If the two nodes are in fact on the same net (assuming conductive FETs) then the device is not considered to be subject to damage. The potential for charging damage is assessed by considering how different and how large the antennas on the two nodes are. If the possibility of damage is considered to be too large, then a shunt device may be inserted from gate to source/drain, the antenna on one or the other of the nodes may be redesigned to balance the charging, or an additional dummy antenna may be added to one or the other node to balance the design. The dummy antenna may be connected with an otherwise non-functional transistor as a "series device."

[0020] During processing, the ultimate circuit configuration is

not complete, so at each level of wiring (M1, M2, etc.) the charging situation is re-assessed. The total number of nodes to be examined reduces as higher levels of wiring are considered, until there is effectively only one single node at the final wiring level. Various degrees of refinement are possible, depending on the specifics of the particular technology. For example, the damage may be observed to occur only on devices of a particular type, and in a particular configuration. One such example is that "thick"(>2nm) pfets with high-aspect ratio vias on the gate node may be the only susceptible configuration, and all others may be safely ignored.

- [0021] Figure 4 shows of the invention in flowchart form. More specifically, Figure 4 shows that the invention prevents damage from current flow between the source/drain and gate of SOI transistors by tracing electrical nets in the integrated circuit design 40, identifying SOI transistors that may have a voltage differential between the source/drain and gate as potentially damaged SOI transistors 42 (based on the tracing of the electrical nets), and connecting a shunt device to one of the source/drain and the gate of each of the potentially damaged SOI transistors 44. In addition, the invention can also connect compensating con-

ductors to the potentially damaged transistor, possibly through series device 46. The series device and the compensating conductor eliminate the potential for charging damage between the source/drain and the gate of each of the potentially damaged SOI transistors. As mentioned above, the tracing process is performed assuming all metals and diffusions are conductive. Further, the tracing, the identifying, and the connecting processes are repeated at each level of wiring within the integrated circuit design.

- [0022] The invention uses a number of different processes to determine whether a voltage differential may exist between the source/drain and gate of each SOI transistor. For example, the invention compares aspect ratios of vias connected to the source/drain and the gate of each of the SOI transistors to determine whether a voltage differential may exist between the source/drain and the gate. As mentioned above, the physical design of the conductive shapes that are connected to the gate and source/drain are compared to determine if such conductive shapes will act in similar manners as antennae with respect to charge accumulation. This can be accomplished using any conventional shapes processing program. Therefore, the invention obtains the length, width, height, etc. dimensions

of the various conductors from the conventional shapes processing program and compares these different shapes. For example, a via embedded in a long thin metal wire will have different antenna characteristics than a via within a wide plate. If the shapes are not balanced, the charge accumulation is not likely to be balanced.

- [0023] In addition, the invention can compare chip locations of conductors connected to the source/drain and the gate of each of the SOI transistors to determine whether a voltage differential may exist between the source/drain and the gate. Again, using any conventional integrated circuit model program the location, direction, length, etc. of the conductors connected to the gate and to the source/drain are compared to determine whether their different positions within the chip (or circuit) would cause a voltage differential. Further, the proximity of other conductive lines is considered by the invention. Therefore, other conductive lines that are within a predetermined proximity (and/or that carry a predetermined voltage level) will be considered to leak a certain predetermined percentage of the voltage to the conductor in question. Also, the invention can compare parasitic capacitances of conductors connected to the source/drain and the gate of each of the

SOI transistors to determine whether a voltage differential may exist between the source/drain and the gate. Thus, the invention uses any conventional parasitic capacitance calculator to determine the parasitic capacitance of a conductor connected to the gate and compares this parasitic capacitance to a conductor connected to the source/drain.

- [0024] For example, Figure 1 illustrates a potentially damaged SOI transistor 10 that has its gate connected to a plate via 14 and its source/drain connected to a trench via 12 (or vice versa). As mentioned above, the invention identifies this SOI transistor 10 as having the potential to be damaged because charge accumulation on the plate via 14 will be substantially different than the trench via 12 because the long narrow shape of the trench via-antenna 12 provides a greater antenna effect and will accumulate a more positive potential than will the plate via-antenna 14. As shown in Figure 2, the invention adds a shunt device 20 connected to either the source/drain or gate. The shunt device is, for example, a diode-connected transistor that has its gate tied to its source. The structure can also include a compensating conductor 30 connected through an additional series device 36 as shown in Figure 3. Also, the invention can add more series devices 32 and potentially

more conductive features 34, if needed, in order to balance the charging effects.

[0025] As shown in Figure 2, the shunt device should be positioned in parallel with the SOI transistor. Thus, the shunt device can be positioned between a first conductor connected to the source/drain of the SOI transistor and a second conductor connected to the gate of the SOI transistor. Alternatively, a series device can be positioned between a first conductor connected to the SOI transistor and a second conductor (e.g., 30, 34) that is not connected to the SOI transistor. Also, the invention can further include additional series devices (e.g., 32, 36), wherein the first series device is connected to a first conductor and the second series device is connected to a second conductor, where the first conductor is connected to the source/drain of the SOI transistor and the second conductor is connected to the gate of the SOI transistor.

[0026] Once the susceptible devices are identified by the tracing program, the designer may choose the most appropriate means of eliminating the potential for damage. For example, a very large damage-susceptible device may be readily protected by the addition of a shunt device, where the additional leakage across the shunt device will not affect

normal circuit operation. For locations where the leakage is unacceptable, a compensating antenna may be added. Additional capacitive load is the penalty for this approach. For locations where neither leakage nor capacitive load is acceptable to the normal circuit operation, connection of the compensating antenna through the series device is the best option.

- [0027] The additional conductive features 30, 34 and series devices 32, 36 shown in Figure 3 are merely exemplary devices added by the application. These examples primarily add the series devices and conductive features to balance the antenna affects due to via configuration differences. Series devices and conductive features may be added to compensate for other differences such as proximity of conductive lines, uneven positioning within the chip, etc. In addition, other devices such as large FETs can be added to compensate for other unbalances. including parasitic capacitance. The compensating devices and conductive shapes are added to the circuit to eliminate the potential for charging damage between the source/drain and the gate of the SOI transistor. Further, these devices and compensating structures perform no function other than eliminating the potential for charging damage. The inven-

tion provides rapid design flow from the checking algorithm and repair options provided, increased flexibility in choice of processes and tooling that might damage less robustly designed products, and improved reliability and yield in damage-free SOI products.

- [0028] While the invention has been described in terms of preferred embodiments, those skilled in the art will recognize that the invention can be practiced with modification within the spirit and scope of the appended claims.
